

# Review #4: Polynomial Arithmetic

Carl Stitz and Jeff Zeager  
Edited by Sean Fitzpatrick

May 18, 2016

In this handout, we review the arithmetic of polynomials. What precisely is a polynomial?<sup>1</sup>

**Definition 1.** A polynomial is a sum of terms each of which is a real number or a real number multiplied by one or more variables to natural number powers.

Some examples of polynomials are  $x^2 + x\sqrt{3} + 4$ ,  $27x^2y + \frac{7x}{2}$  and 6. Things like  $3\sqrt{x}$ ,  $4x - \frac{2}{x+1}$  and  $13x^{2/3}y^2$  are not polynomials. (Do you see why not?) Below we review some of the terminology associated with polynomials.

**Definition 2. Polynomial Vocabulary**

- **Constant Terms:** Terms in polynomials without variables are called constant terms.
- **Coefficient:** In non-constant terms, the real number factor in the expression is called the coefficient of the term.
- **Degree:** The degree of a non-constant term is the sum of the exponents on the variables in the term; non-zero constant terms are defined to have degree 0. The degree of a polynomial is the highest degree of the nonzero terms.
- **Like Terms:** Terms in a polynomial are called like terms if they have the same variables each with the same corresponding exponents.
- **Simplified:** A polynomial is said to be simplified if all arithmetic operations have been completed and there are no longer any like terms.
- **Classification by Number of Terms:** A simplified polynomial is called a
  - monomial if it has exactly one nonzero term
  - binomial if it has exactly two nonzero terms
  - trinomial if it has exactly three nonzero terms

For example,  $x^2 + x\sqrt{3} + 4$  is a trinomial of degree 2. The coefficient of  $x^2$  is 1 and the constant term is 4. The polynomial  $27x^2y + \frac{7x}{2}$  is a binomial of degree 3 ( $x^2y = x^2y^1$ ) with constant term 0.

The concept of ‘like’ terms really amounts to finding terms which can be combined using the Distributive Property. For example, in the polynomial  $17x^2y - 3xy^2 + 7xy^2$ ,  $-3xy^2$  and  $7xy^2$  are

---

<sup>1</sup>In this handout we focus on polynomial expressions. When you encounter polynomials in your textbook (and courses) it will usually be in the context of polynomial functions of the form  $f(x) = a_nx^n + \cdots + a_1x + a_0$ .

like terms, since they have the same variables with the same corresponding exponents. This allows us to combine these two terms as follows:

$$17x^2y - 3xy^2 + 7xy^2 = 17x^2y + (-3)xy^2 + 7xy^2 + 17x^2y + (-3 + 7)xy^2 = 17x^2y + 4xy^2$$

Note that even though  $17x^2y$  and  $4xy^2$  have the same variables, they are not like terms since in the first term we have  $x^2$  and  $y = y^1$  but in the second we have  $x = x^1$  and  $y = y^2$  so the corresponding exponents aren't the same. Hence,  $17x^2y + 4xy^2$  is the simplified form of the polynomial.

There are four basic operations we can perform with polynomials: addition, subtraction, multiplication and division. The first three of these operations follow directly from properties of real number arithmetic and will be discussed together first. Division, on the other hand, is a bit more complicated and will be discussed separately.

## 1 Polynomial Addition, Subtraction and Multiplication.

Adding and subtracting polynomials comes down to identifying like terms and then adding or subtracting the coefficients of those like terms. Multiplying polynomials comes to us courtesy of the Generalized Distributive Property.

**Theorem 1. Generalized Distributive Property:** To multiply a quantity of  $n$  terms by a quantity of  $m$  terms, multiply each of the  $n$  terms of the first quantity by each of the  $m$  terms in the second quantity and add the resulting  $n \cdot m$  terms together.

In particular, Theorem 1 says that, before combining like terms, a product of an  $n$ -term polynomial and an  $m$ -term polynomial will generate  $(n \cdot m)$ -terms. For example, a binomial times a trinomial will produce six terms some of which may be like terms. Thus the simplified end result may have fewer than six terms but you will start with six terms.

A special case of Theorem 1 is the famous F.O.I.L., listed here:<sup>2</sup>

**Theorem 2. F.O.I.L:** The terms generated from the product of two binomials:  $(a + b)(c + d)$  can be verbalized as follows “Take the sum of:

- the product of the First terms  $a$  and  $c$ ,  $ac$
- the product of the Outer terms  $a$  and  $d$ ,  $ad$
- the product of the Inner terms  $b$  and  $c$ ,  $bc$
- the product of the Last terms  $b$  and  $d$ ,  $bd$ .”

That is,  $(a + b)(c + d) = ac + ad + bc + bd$ .

Theorem 1 is best proved using the technique known as Mathematical Induction which is covered in Math 2000. The result is really nothing more than repeated applications of the Distributive Property so it seems reasonable and we'll use it without proof for now. The other major piece of polynomial multiplication is the law of exponents  $a^n a^m = a^{n+m}$ . The Commutative and Associative Properties of addition and multiplication are also used extensively. We put all of these properties to good use in the next example.

---

<sup>2</sup>We caved to peer pressure on this one. Apparently all of the cool Precalculus books have FOIL in them even though it's redundant once you know how to distribute multiplication across addition. In general, we don't like mechanical short-cuts that interfere with a student's understanding of the material and FOIL is one of the worst.

Example 1. Perform the indicated operations and simplify.

1.  $(3x^2 - 2x + 1) - (7x - 3)$
2.  $4xz^2 - 3z(xz - x + 4)$
3.  $(2t + 1)(3t - 7)$
4.  $(3y - \sqrt[3]{2})(9y^2 + 3\sqrt[3]{2}y + \sqrt[3]{4})$
5.  $\left(4w - \frac{1}{2}\right)^2$
6.  $[2(x + h) - (x + h)^2] - (2x - x^2)$

Solution.

1. We begin ‘distributing the negative’, then we rearrange and combine like terms:

$$\begin{aligned}
 (3x^2 - 2x + 1) - (7x - 3) &= 3x^2 - 2x + 1 - 7x + 3 && \text{Distribute} \\
 &= 3x^2 - 2x - 7x + 1 + 3 && \text{Rearrange terms} \\
 &= 3x^2 - 9x + 4 && \text{Combine like terms}
 \end{aligned}$$

Our answer is  $3x^2 - 9x + 4$ .

2. Following in our footsteps from the previous example, we first distribute the  $-3z$  through, then rearrange and combine like terms.

$$\begin{aligned}
 4xz^2 - 3z(xz - x + 4) &= 4xz^2 - 3z(xz) + 3z(x) - 3z(4) && \text{Distribute} \\
 &= 4xz^2 - 3xz^2 + 3xz - 12z && \text{Multiply} \\
 &= xz^2 + 3xz - 12z && \text{Combine like terms}
 \end{aligned}$$

We get our final answer:  $xz^2 + 3xz - 12z$

3. At last, we have a chance to use our F.O.I.L. technique:

$$\begin{aligned}
 (2t + 1)(3t - 7) &= (2t)(3t) + (2t)(-7) + (1)(3t) + (1)(-7) && \text{F.O.I.L.} \\
 &= 6t^2 - 14t + 3t - 7 && \text{Multiply} \\
 &= 6t^2 - 11t - 7 && \text{Combine like terms}
 \end{aligned}$$

We get  $6t^2 - 11t - 7$  as our final answer.

4. We use the Generalized Distributive Property here, multiplying each term in the second quantity first by  $3y$ , then by  $-\sqrt[3]{2}$ :

$$\begin{aligned}
 (3y - \sqrt[3]{2})(9y^2 + 3\sqrt[3]{2}y + \sqrt[3]{4}) &= 3y(9y^2) + 3y(3\sqrt[3]{2}y) + 3y(\sqrt[3]{4}) \\
 &\quad - \sqrt[3]{2}(9y^2) - \sqrt[3]{2}(3\sqrt[3]{2}y) - \sqrt[3]{2}(\sqrt[3]{4}) \\
 &= 27y^3 + 9y^2\sqrt[3]{2} + 3y\sqrt[3]{4} - 9y^2\sqrt[3]{2} - 3y\sqrt[3]{4} - \sqrt[3]{8} \\
 &= 27y^3 + 9y^2\sqrt[3]{2} - 9y^2\sqrt[3]{2} + 3y\sqrt[3]{4} - 3y\sqrt[3]{4} - 2 \\
 &= 27y^3 - 2
 \end{aligned}$$

To our surprise and delight, this product reduces to  $27y^3 - 2$ .

5. Since exponents do not distribute across powers,  $(4w - \frac{1}{2})^2 \neq (4w)^2 - (\frac{1}{2})^2$ . (We know you knew that.) Instead, we proceed as follows:

$$\begin{aligned}
 \left(4w - \frac{1}{2}\right)^2 &= \left(4w - \frac{1}{2}\right) \left(4w - \frac{1}{2}\right) \\
 &= (4w)(4w) + (4w)\left(-\frac{1}{2}\right) + \left(-\frac{1}{2}\right)(4w) + \left(-\frac{1}{2}\right)\left(-\frac{1}{2}\right) && \text{F.O.I.L.} \\
 &= 16w^2 - 2w - 2w + \frac{1}{4} && \text{Multiply} \\
 &= 16w^2 - 4w + \frac{1}{4} && \text{Combine like terms}
 \end{aligned}$$

Our (correct) final answer is  $16w^2 - 4w + \frac{1}{4}$ .

6. Our last example has two levels of grouping symbols. We begin simplifying the quantity inside the brackets, squaring out the binomial  $(x + h)^2$  in the same way we expanded the square in our last example:

$$(x + h)^2 = (x + h)(x + h) = (x)(x) + (x)(h) + (h)(x) + (h)(h) = x^2 + 2xh + h^2$$

When we substitute this into our expression, we envelope it in parentheses, as usual, so we don't forget to distribute the negative.

$$\begin{aligned}
 [2(x + h) - (x + h)^2] - (2x - x^2) &= [2(x + h) - (x^2 + 2xh + h^2)] - (2x - x^2) && \text{Substitute} \\
 &= [2x + 2h - x^2 - 2xh - h^2] - (2x - x^2) && \text{Distribute} \\
 &= 2x + 2h - x^2 - 2xh - h^2 - 2x + x^2 && \text{Distribute} \\
 &= 2x - 2x + 2h - x^2 + x^2 - 2xh - h^2 && \text{Rearrange terms} \\
 &= 2h - 2xh - h^2 && \text{Combine like terms}
 \end{aligned}$$

We find no like terms in  $2h - 2xh - h^2$  so we are finished.  $\square$

We conclude our discussion of polynomial multiplication by showcasing two special products which happen often enough they should be committed to memory.

**Theorem 3. Special Products:** Let  $a$  and  $b$  be real numbers:

- Perfect Square:  $(a + b)^2 = a^2 + 2ab + b^2$  and  $(a - b)^2 = a^2 - 2ab + b^2$
- Difference of Two Squares:  $(a - b)(a + b) = a^2 - b^2$

The formulas in Theorem 3 can be verified by working through the multiplication.<sup>3</sup>

## 2 Polynomial Long Division.

We now turn our attention to polynomial long division. Dividing two polynomials follows the same algorithm, in principle, as dividing two natural numbers so we review that process first. Suppose we wished to divide 2585 by 79. The standard division tableau is given below.

---

<sup>3</sup>These are both special cases of F.O.I.L.

$$\begin{array}{r}
32 \\
79 \overline{) 2585} \\
\underline{- 237} \downarrow \\
215 \\
\underline{- 158} \\
57
\end{array}$$

In this case, 79 is called the divisor, 2585 is called the dividend, 32 is called the quotient and 57 is called the remainder. We can check our answer by showing:

$$\text{dividend} = (\text{divisor})(\text{quotient}) + \text{remainder}$$

or in this case,  $2585 = (79)(32) + 57\checkmark$ . We hope that the long division tableau evokes warm, fuzzy memories of your formative years as opposed to feelings of hopelessness and frustration. If you experience the latter, keep in mind that the Division Algorithm essentially is a two-step process, iterated over and over again. First, we guess the number of times the divisor goes into the dividend and then we subtract off our guess. We repeat those steps with what's left over until what's left over (the remainder) is less than what we started with (the divisor). That's all there is to it!

The division algorithm for polynomials has the same basic two steps but when we subtract polynomials, we must take care to subtract like terms only. As a transition to polynomial division, let's write out our previous division tableau in expanded form.

$$\begin{array}{r}
3 \cdot 10 + 2 \\
7 \cdot 10 + 9 \overline{) 2 \cdot 10^3 + 5 \cdot 10^2 + 8 \cdot 10 + 5} \\
\underline{-(2 \cdot 10^3 + 3 \cdot 10^2 + 7 \cdot 10)} \quad \downarrow \\
2 \cdot 10^2 + 1 \cdot 10 + 5 \\
\underline{-(1 \cdot 10^2 + 5 \cdot 10 + 8)} \\
5 \cdot 10 + 7
\end{array}$$

Written this way, we see that when we line up the digits we are really lining up the coefficients of the corresponding powers of 10 - much like how we'll have to keep the powers of  $x$  lined up in the same columns. The big difference between polynomial division and the division of natural numbers is that the value of  $x$  is an unknown quantity. So unlike using the known value of 10, when we subtract there can be no regrouping of coefficients as in our previous example. (The subtraction  $215 - 158$  requires us to 'regroup' or 'borrow' from the tens digit, then the hundreds digit.) This actually makes polynomial division easier.<sup>4</sup> Before we dive into examples, we first state a theorem telling us when we can divide two polynomials, and what to expect when we do so.

**Theorem 4. Polynomial Division:** Let  $d$  and  $p$  be nonzero polynomials where the degree of  $p$  is greater than or equal to the degree of  $d$ . There exist two unique polynomials,  $q$  and  $r$ , such that  $p = d \cdot q + r$ , where either  $r = 0$  or the degree of  $r$  is strictly less than the degree of  $d$ .

Essentially, Theorem 4 tells us that we can divide polynomials whenever the degree of the divisor is less than or equal to the degree of the dividend. We know we're done with the division when the polynomial left over (the remainder) has a degree strictly less than the divisor. It's time to walk through a few examples to refresh your memory.

<sup>4</sup>In our opinion - you can judge for yourself.

Example 2. Perform the indicated division. Check your answer by showing

$$\text{dividend} = (\text{divisor})(\text{quotient}) + \text{remainder}$$

1.  $(x^3 + 4x^2 - 5x - 14) \div (x - 2)$
2.  $(2t + 7) \div (3t - 4)$
3.  $(6y^2 - 1) \div (2y + 5)$
4.  $(w^3) \div (w^2 - \sqrt{2})$ .

Solution.

1. To begin  $(x^3 + 4x^2 - 5x - 14) \div (x - 2)$ , we divide the first term in the dividend, namely  $x^3$ , by the first term in the divisor, namely  $x$ , and get  $\frac{x^3}{x} = x^2$ . This then becomes the first term in the quotient. We proceed as in regular long division at this point: we multiply the entire divisor,  $x - 2$ , by this first term in the quotient to get  $x^2(x - 2) = x^3 - 2x^2$ . We then subtract this result from the dividend.

$$\begin{array}{r} x^2 \\ x-2 \overline{) x^3 + 4x^2 - 5x - 14} \\ \underline{-(x^3 - 2x^2)} \quad \downarrow \\ 6x^2 - 5x \end{array}$$

Now we ‘bring down’ the next term of the quotient, namely  $-5x$ , and repeat the process. We divide  $\frac{6x^2}{x} = 6x$ , and add this to the quotient polynomial, multiply it by the divisor (which yields  $6x(x - 2) = 6x^2 - 12x$ ) and subtract.

$$\begin{array}{r} x^2 + 6x \\ x-2 \overline{) x^3 + 4x^2 - 5x - 14} \\ \underline{-(x^3 - 2x^2)} \quad \downarrow \\ 6x^2 - 5x \quad \downarrow \\ \underline{-(6x^2 - 12x)} \quad \downarrow \\ 7x - 14 \end{array}$$

Finally, we ‘bring down’ the last term of the dividend, namely  $-14$ , and repeat the process. We divide  $\frac{7x}{x} = 7$ , add this to the quotient, multiply it by the divisor (which yields  $7(x - 2) = 7x - 14$ ) and subtract.

$$\begin{array}{r} x^2 + 6x + 7 \\ x-2 \overline{) x^3 + 4x^2 - 5x - 14} \\ \underline{-(x^3 - 2x^2)} \\ 6x^2 - 5x \\ \underline{-(6x^2 - 12x)} \\ 7x - 14 \\ \underline{-(7x - 14)} \\ 0 \end{array}$$

In this case, we get a quotient of  $x^2 + 6x + 7$  with a remainder of 0. To check our answer, we compute

$$(x - 2)(x^2 + 6x + 7) + 0 = x^3 + 6x^2 + 7x - 2x^2 - 12x - 14 = x^3 + 4x^2 - 5x - 14 \checkmark$$

2. To compute  $(2t + 7) \div (3t - 4)$ , we start as before. We find  $\frac{2t}{3t} = \frac{2}{3}$ , so that becomes the first (and only) term in the quotient. We multiply the divisor  $(3t - 4)$  by  $\frac{2}{3}$  and get  $2t - \frac{8}{3}$ . We subtract this from the dividend and get  $\frac{29}{3}$ .

$$\begin{array}{r} \frac{2}{3} \\ 3t-4 \overline{) 2t + 7} \\ \underline{-(2t - \frac{8}{3})} \\ \frac{29}{3} \end{array}$$

Our answer is  $\frac{2}{3}$  with a remainder of  $\frac{29}{3}$ . To check our answer, we compute

$$(3t - 4) \left( \frac{2}{3} \right) + \frac{29}{3} = 2t - \frac{8}{3} + \frac{29}{3} = 2t + \frac{21}{3} = 2t + 7 \checkmark$$

3. When we set-up the tableau for  $(6y^2 - 1) \div (2y + 5)$ , we must first issue a ‘placeholder’ for the ‘missing’  $y$ -term in the dividend,  $6y^2 - 1 = 6y^2 + 0y - 1$ . We then proceed as before. Since  $\frac{6y^2}{2y} = 3y$ ,  $3y$  is the first term in our quotient. We multiply  $(2y + 5)$  times  $3y$  and subtract it from the dividend. We bring down the  $-1$ , and repeat.

$$\begin{array}{r} 3y - \frac{15}{2} \\ 2y+5 \overline{) 6y^2 + 0y - 1} \\ \underline{-(6y^2 + 15y)} \quad \downarrow \\ -15y - 1 \\ \underline{-(-15y - \frac{75}{2})} \\ \frac{73}{2} \end{array}$$

Our answer is  $3y - \frac{15}{2}$  with a remainder of  $\frac{73}{2}$ . To check our answer, we compute:

$$(2y + 5) \left( 3y - \frac{15}{2} \right) + \frac{73}{2} = 6y^2 - 15y + 15y - \frac{75}{2} + \frac{73}{2} = 6y^2 - 1 \checkmark$$

4. For our last example, we need ‘placeholders’ for both the divisor  $w^2 - \sqrt{2} = w^2 + 0w - \sqrt{2}$  and the dividend  $w^3 = w^3 + 0w^2 + 0w + 0$ . The first term in the quotient is  $\frac{w^3}{w^2} = w$ , and when we multiply and subtract this from the dividend, we’re left with just  $0w^2 + w\sqrt{2} + 0 = w\sqrt{2}$ .

$$\begin{array}{r} w \\ w^2+0w-\sqrt{2} \overline{) w^3 + 0w^2 + 0w + 0} \\ \underline{-(w^3 + 0w^2 - w\sqrt{2})} \quad \downarrow \\ 0w^2 + w\sqrt{2} + 0 \end{array}$$

Since the degree of  $w\sqrt{2}$  (which is 1) is less than the degree of the divisor (which is 2), we are done.<sup>5</sup> Our answer is  $w$  with a remainder of  $w\sqrt{2}$ . To check, we compute:

$$\left(w^2 - \sqrt{2}\right)w + w\sqrt{2} = w^3 - w\sqrt{2} + w\sqrt{2} = w^3 \checkmark \quad \square$$

---

<sup>5</sup>Since  $\frac{0w^2}{w^2} = 0$ , we could proceed, write our quotient as  $w + 0$ , and move on... but even pedants have limits.

### 3 Exercises

In Exercises 1 - 15, perform the indicated operations and simplify.

1.  $(4 - 3x) + (3x^2 + 2x + 7)$
2.  $t^2 + 4t - 2(3 - t)$
3.  $q(200 - 3q) - (5q + 500)$
4.  $(3y - 1)(2y + 1)$
5.  $\left(3 - \frac{x}{2}\right)(2x + 5)$
6.  $-(4t + 3)(t^2 - 2)$
7.  $2w(w^3 - 5)(w^3 + 5)$
8.  $(5a^2 - 3)(25a^4 + 15a^2 + 9)$
9.  $(x^2 - 2x + 3)(x^2 + 2x + 3)$
10.  $(\sqrt{7} - z)(\sqrt{7} + z)$
11.  $(x - \sqrt[3]{5})^3$
12.  $(x - \sqrt[3]{5})(x^2 + x\sqrt[3]{5} + \sqrt[3]{25})$
13.  $(w - 3)^2 - (w^2 + 9)$
14.  $(x + h)^2 - 2(x + h) - (x^2 - 2x)$
15.  $(x - [2 + \sqrt{5}])(x - [2 - \sqrt{5}])$

In Exercises 16 - 27, perform the indicated division. Check your answer by showing

$$\text{dividend} = (\text{divisor})(\text{quotient}) + \text{remainder}$$

16.  $(5x^2 - 3x + 1) \div (x + 1)$
17.  $(3y^2 + 6y - 7) \div (y - 3)$
18.  $(6w - 3) \div (2w + 5)$
19.  $(2x + 1) \div (3x - 4)$
20.  $(t^2 - 4) \div (2t + 1)$
21.  $(w^3 - 8) \div (5w - 10)$
22.  $(2x^2 - x + 1) \div (3x^2 + 1)$
23.  $(4y^4 + 3y^2 + 1) \div (2y^2 - y + 1)$
24.  $w^4 \div (w^3 - 2)$
25.  $(5t^3 - t + 1) \div (t^2 + 4)$
26.  $(t^3 - 4) \div (t - \sqrt[3]{4})$
27.  $(x^2 - 2x - 1) \div (x - [1 - \sqrt{2}])$

In Exercises 28 - 33 verify the given formula by showing the left hand side of the equation simplifies to the right hand side of the equation.

28. Perfect Cube:  $(a + b)^3 = a^3 + 3a^2b + 3ab^2 + b^3$
29. Difference of Cubes:  $(a - b)(a^2 + ab + b^2) = a^3 - b^3$
30. Sum of Cubes:  $(a + b)(a^2 - ab + b^2) = a^3 + b^3$
31. Perfect Quartic:  $(a + b)^4 = a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4$
32. Difference of Quartics:  $(a - b)(a + b)(a^2 + b^2) = a^4 - b^4$
33. Sum of Quartics:  $(a^2 + ab\sqrt{2} + b^2)(a^2 - ab\sqrt{2} + b^2) = a^4 + b^4$
34. With help from your classmates, determine under what conditions  $(a + b)^2 = a^2 + b^2$ . What about  $(a + b)^3 = a^3 + b^3$ ? In general, when does  $(a + b)^n = a^n + b^n$  for a natural number  $n \geq 2$ ?

## 4 Answers

1.  $3x^2 - x + 11$
